Abstract

The rapid expansion of the automobile sector in developing nations has intensified road safety concerns, particularly in congested urban environments where human error accounts for approximately 90% of all accidents. This paper presents and experimentally validates an integrated Advanced Driver Assistance System (ADAS) for electric vehicles comprising three complementary safety modules: a Forward Collision Avoidance System (FCAS) employing an HC-SR04 ultrasonic sensor interfaced with an Arduino Uno R3 to detect frontal obstacles within 50 cm and trigger automatic braking via an L298N motor driver; a Blind Spot Detection (BSD) system using three directional ultrasonic sensors with colour-coded LED alerts for lateral and rear blind zones; and a Driver Drowsiness Detection (DDD) system implemented on a Raspberry Pi 4 Model B using real-time computer vision, monitoring the Eye Aspect Ratio (EAR), Mouth Opening Ratio (MOR), and Nose Length Ratio (NLR) via the Dlib 68-point facial landmark model. Experimental results confirm reliable real-time operation of each module. The FCAS successfully engaged braking upon obstacle detection; the BSD system accurately identified directional blind-spot intrusions; and the DDD algorithm correctly classified four driver states: Active, Drowsy, Sleeping, and Head Bending with consistent accuracy across all test subjects. The proposed system is cost-effective (approximately USD 25 for hardware), modular, and scalable, providing a practical safety upgrade for commuter-segment vehicles currently underserved by commercial ADAS solutions.

Keywords: *Electric Vehicle Safety; ADAS Technology; Automatic Braking System; Blind Spot Detection; Driver Drowsiness Detection; Ultrasonic Sensor; Eye Aspect Ratio; Facial Landmark Detection*

1. Introduction

The global proliferation of motor vehicles has brought a corresponding rise in road traffic accidents. In developing nations, insufficient infrastructure and high traffic density have made road safety a critical

public concern. Statistical evidence consistently indicates that approximately 90% of road accidents are attributable to human error, while road conditions (5%) and vehicle mechanical faults (5%) account for the remainder [1]. This distribution underscores the substantial potential of driver-assistance technologies to reduce accident rates.

The Automatic Emergency Braking (AEB) system first introduced in 2009 for heavy motor vehicles and subsequently adapted for light vehicles represents one of the most impactful ADAS interventions to date. By autonomously monitoring the vehicle's forward path and applying braking force when an imminent collision is detected, AEB directly compensates for delayed human reaction. Modern AEB implementations combine radar and camera technologies to identify hazardous objects and intervene before the driver responds [2, 3].

Despite these advances in premium vehicle segments, commuter-segment vehicles continue to offer only minimal safety features largely limited to airbags and basic engine fault diagnostics. Addressing this gap, the present study develops and experimentally validates a multi-module safety system integrating a Forward Collision Avoidance System (FCAS) using automatic braking, Blind Spot Detection system with directional LED alerts, and Driver Drowsiness Detection (DDD) system based on real-time facial landmark analysis. Together, these modules provide comprehensive, low-cost driver assistance tailored for modern electric vehicles in the commuter segment. [Fig.1]

Fig. 1. Schematic overview of an Automatic Braking System

2. Literature Review

Several studies have investigated ultrasonic sensor-based obstacle detection for automotive safety applications. Sharma et al. [4] presented a detailed fabrication-level analysis of automatic braking systems, confirming the mechanical feasibility of such implementations in real vehicles. Ram and Kumar [5] demonstrated a basic ultrasonic braking prototype achieving consistent distance measurements with an Arduino platform, establishing proof-of-concept for low-cost AEB.

In the domain of driver drowsiness detection, Sahayadhas et al. [6] provided a comprehensive review of sensor-based fatigue monitoring methods, identifying camera-based facial analysis as the most practical non-intrusive approach for production vehicles. Danisman et al. [7] specifically validated eye-blink pattern analysis using camera systems for binary drowsiness classification. Liu et al. [8] proposed eyelid movement metrics consistent with the Eye Aspect Ratio computation employed in this study.

3. Research Objective

Existing literature predominantly addresses individual safety subsystems in isolation. The primary contribution of this paper is the integration of three complementary modules FCAS, BSD, and DDD within a single cost-effective hardware platform. This provides a holistic safety solution specifically aimed at the underserved commuter vehicle segment, where commercial ADAS systems remain economically inaccessible [9].

4. System Design and Hardware

The proposed system is built around two primary processing units; an Arduino Uno R3, which handles sensor interfacing and motor control for the FCAS and BSD modules, and a Raspberry Pi 4 Model B (4 GB), [Fig.2] dedicated to the vision-based DDD module. The complete hardware inventory is summarised in [Table 1](#).

Table 1 System Hardware Components

Module	Component	Function
FCAS	HC-SR04 Ultrasonic Sensor (Front)	Frontal obstacle distance measurement
FCAS	Arduino Uno R3	Sensor data processing and motor control
FCAS	L298N Motor Driver	DC motor braking actuation
FCAS	14.4V Li-ion Battery + SPST Switch	Power supply with manual isolation
BSD	HC-SR04 $\times$ 3 (Left, Right, Rear)	Lateral and rear blind-spot detection
BSD	LEDs: White, Green, Blue	Directional obstacle indication
BSD	Piezo Buzzer	Audible proximity warning
DDD	Raspberry Pi 4 Model B (4 GB)	Computer vision pipeline host
DDD	Logitech C270 USB Camera	Real-time driver face capture
DDD	Piezo Buzzer (GPIO18)	Drowsiness alert output

Fig.2. Experimental set-up

5. Forward Collision Avoidance System

5.1 Working Principle

The Forward Collision Avoidance System employs an HC-SR04 ultrasonic sensor mounted at the front of the vehicle. The sensor emits 40 kHz ultrasonic pulses via its transmitter; upon striking an obstacle, the pulse reflects back and is detected by the receiver. The Arduino Uno R3 measures the round-trip travel time and computes obstacle distance using the speed-of-sound formula:

$$Distance \text{ (cm)} = [Time \text{ (}\mu s) \times 0.0343] \div 2$$

When the computed distance falls at or below the safety threshold of 50 cm, the Arduino signals the L298N motor driver to apply braking, bringing the vehicle to a controlled stop. The 50 cm threshold was empirically selected to provide a sufficient reaction margin at typical urban and low-speed driving conditions [10].

5.2 Hardware Connections

Table 2 details the pin mapping between the Arduino Uno R3 and the four ultrasonic sensors. Table 3 shows the L298N motor driver connections for controlling the four DC geared motors arranged in left and right pairs [11].

Table 2 Arduino Uno R3 to Ultrasonic Sensor Pin Mapping

Arduino Pin	Connected Component
D2 (Trig) / D3 (Echo)	Front Ultrasonic Sensor — Trigger / Echo

Arduino Pin	Connected Component
D4 (Trig) / D5 (Echo)	Left Ultrasonic Sensor — Trigger / Echo
D6 (Trig) / D7 (Echo)	Right Ultrasonic Sensor — Trigger / Echo
D8 (Trig) / D9 (Echo)	Rear Ultrasonic Sensor — Trigger / Echo
D10 / D11 / D12	White LED (Left) / Green LED (Right) / Blue LED (Rear)
5V / GND	Breadboard positive and negative power rails

Table 3 L298N Motor Driver Output Connections

L298N Output	Motor Connection
OUT1 / OUT2	Left Motor Pair — Positive (+) / Negative (–)
OUT3 / OUT4	Right Motor Pair — Positive (+) / Negative (–)

6. Blind Spot Detection System

6.1 System Overview

The Blind Spot Detection system monitors three critical zones left, right, and rear that are not directly visible to the driver through mirrors. The system uses three HC-SR04 sensors, each paired with a dedicated colour-coded LED and a shared audible piezo buzzer [Table 4](#). When an obstacle is detected within the 50 cm warning zone in any direction, the corresponding LED activates and the buzzer sounds [12].

Table 4 LED Colour to Sensor Direction Mapping

Sensor Direction	LED Colour	Arduino Pin	Risk Scenario
Left	White	D10	Lane change; left turns; overtaking from left
Right	Green	D11	Lane switching to right; highway merging
Rear	Blue	D12	Reversing; parking; small obstacles behind vehicle

6.2 Detection Logic

Each HC-SR04 sensor continuously scans its assigned blind spot zone. The measured distance is compared against the 50 cm threshold:

- If distance $\leq$ 50 cm: the directional LED activates and the buzzer sounds — obstacle present in blind spot.
- If distance $>$ 50 cm: LED off, buzzer silent — zone clear.

To prevent acoustic cross-talk between simultaneously active sensors, sequential triggering is employed with 50–100 ms inter-sensor delays. Non-blocking timing is implemented using Arduino's millis function to ensure continuous operation of all channels without program stalls [Table 5].

6.3 Raspberry Pi and Buzzer Wiring

Table 5 Raspberry Pi 4 GPIO — Piezo Buzzer Connection

Buzzer Terminal Raspberry Pi GPIO
Positive (+) — Red wire GPIO18 (Physical Pin 12)
Negative (−) — Black wire GND (Physical Pin 6)

7. Driver Drowsiness Detection System

7.1 Motivation

Drowsy driving is a major contributor to road fatalities, with impairment levels comparable to alcohol intoxication according to National Highway Traffic Safety Administration (NHTSA) and World Health Organization (WHO). Fatigue accumulates particularly during long-distance highway driving, night shifts, and monotonous road conditions. Unlike alcohol impairment, drowsiness produces no externally visible behavioural cues and goes undetected by law enforcement, making automated in-vehicle detection systems indispensable.

7.2 Dlib 68-Point Facial Landmark Model

The drowsiness detection pipeline is built on Dlib's pre-trained 68-point facial landmark model. The model uses a HOG (Histogram of Oriented Gradients) + SVM-based face detector to locate the face region, followed by supervised landmark prediction using the `shape_predictor_68_face_landmarks.dat` model [Fig.3]. The 68 landmarks are distributed across facial regions as described in [Table 6](#).

Table 6 Dlib 68-Point Facial Landmark Distribution by Region

Facial Region Landmark Point Range
Jawline 0 – 16
Right Eyebrow 17 – 21
Left Eyebrow 22 – 26
Nose Bridge 27 – 30
Lower Nose 31 – 35
Right Eye 36 – 41
Left Eye 42 – 47
Outer Lips 48 – 59

Facial Region
Landmark Point Range

Inner Lips
60 – 67

Fig.3. Dlib 68-point facial landmark annotation on a human face

7.3 Eye Aspect Ratio (EAR)

The Eye Aspect Ratio quantifies eye openness as the ratio of vertical eye height to horizontal eye width, computed from six peri-ocular landmarks (p1–p6) as follows:

$$EAR = (||p2 - p6|| + ||p3 - p5||) / (2 \times ||p1 - p4||)$$

When the eyes are open, the vertical distances (numerator) are significant, yielding a higher EAR value. Progressive eye closure reduces the numerator toward zero. An EAR below 0.20 sustained over multiple consecutive frames is interpreted as eye closure indicative of drowsiness or microsleep. Typical EAR ranges are given in Table 7.

Table 7 Typical EAR Values by Eye State

Eye State Typical EAR Value
Open (Alert) 0.25 – 0.30
Drowsy / Half-closed 0.20 – 0.25
Closed (Blink / Sleep) < 0.20

7.4 Mouth Opening Ratio (MOR)

The Mouth Opening Ratio measures mouth aperture as an indicator of yawning — a well-established physiological correlate of fatigue. MOR is computed using outer-lip landmarks where p48 and p54 are the horizontal corners, and p51 and p57 are the vertical lip extremities:

$$MOR = ||p51 - p57|| / ||p48 - p54||$$

A temporal threshold requiring $MOR > 0.6$ sustained for more than two seconds is applied to distinguish a genuine yawning event from normal speech or brief mouth opening. Typical MOR values across mouth states are presented in Table 8.

Table 8 Mouth Opening Ratio (MOR) vs. Mouth State

Mouth State Approximate MOR Range
Closed 0.20 – 0.35
Talking / Slightly Open 0.35 – 0.60
Yawning 0.60 – 1.00+

7.5 Nose Length Ratio (NLR)

The Nose Length Ratio captures head-pose variation — particularly forward head tilt (nodding) — which is a characteristic postural precursor to sleep onset. NLR is defined as the ratio of the perceived vertical nose length in image space to a reference facial measurement such as interocular distance:

$$NLR = \text{Vertical nose length (image)} / \text{Interocular distance}$$

A forward head tilt compresses the apparent nose length, reducing NLR below its neutral baseline of approximately 0.90–1.10. A 15–30 frame temporal smoothing window is applied to suppress noise-induced false positives. Expected NLR ranges are summarised in Table 9.

Table 9 Head Pose vs. Nose Length Ratio (NLR)

Head Pose Approximate NLR Range
Neutral (Awake) 0.90 – 1.10
Forward Tilt (Drowsy) 0.08 – 0.90
Backward Tilt 0.08 – 0.70

7.6 Detection Pipeline

The Raspberry Pi 4 captures live video via the Logitech C270 USB camera and processes each frame through the following sequential pipeline: (1) face detection using the Dlib HOG+SVM detector; (2) 68-point facial landmark localisation; (3) computation of EAR, MOR, and NLR from the relevant landmark coordinates; (4) thresholding and temporal consistency evaluation across the sliding frame window; and (5) activation of the piezo buzzer via GPIO18 upon confirmed drowsiness classification. This pipeline runs entirely on the Raspberry Pi 4 without requiring an external server or cloud connection.

8. Results and Discussion

8.1 FCAS and BSD Validation

The Forward Collision Avoidance System successfully applied automatic braking in all test scenarios where an obstacle was introduced within the 50 cm threshold. No false triggers were recorded across repeated open-road test runs. The Blind Spot Detection system correctly activated the colour-coded LED and buzzer alerts for all three sensor directions in every trial. Figures 4–6 confirm the LED activation states observed during hardware testing.

Fig.4. Right sensor detection — Green LED activated (obstacle within 50 cm)

Fig.5. Rear sensor detection — Blue LED activated (obstacle within 50 cm)

Fig.6. Left sensor detection — White LED activated (obstacle within 50 cm)

8.2 Driver Drowsiness Detection Results

Four driver states were evaluated: Active, Drowsy, Sleeping, and Head Bending. Three subjects participated in each state classification session. EAR, MOR, and NLR were plotted over 60 video frames for each condition and analysed. Table 10 summarises the mean metric values and alert status for each state.

Table 10. Mean Facial Metric Values Across Driver States

Driver State	Mean EAR	Mean MOR	Mean NLR	Alert Triggered
Active	0.338	0.016	0.101	No
Drowsy	0.339	0.194	0.107	Yes (EAR dip + MOR spike)
Sleeping	0.140	0.016	0.101	Yes (persistent EAR < 0.20)
Head Bending	0.321	0.033	0.073	Yes (NLR below baseline)

8.2.1 Active State

In the active state, EAR remained stable between 0.25 and 0.35 (mean 0.338), consistent with open and alert eyes. MOR was consistently low at 0.016, indicating no yawning or sustained mouth opening. NLR was steady at 0.101, reflecting an upright and neutral head posture. These three metrics together confirm an alert, attentive driver posture — no alert was triggered [Fig.7].

Fig.7. Facial metric graph — Active state (EAR: 0.338, MOR: 0.016, NLR: 0.101)

8.2.2 Drowsy State

The drowsy state exhibited a notable EAR dip near frame 45 (approaching 0.20), indicating incipient eye closure. MOR showed transient spikes at frames 18 and 50 (mean 0.194), consistent with yawning events. NLR remained stable at 0.107, indicating no significant head movement at this stage. The co-occurrence of an EAR drop and MOR spike within the same temporal window constitutes a robust composite drowsiness signal that reliably triggers the alert [Fig.8].

Fig.8. Facial metric graph — Drowsy state (EAR: 0.339, MOR: 0.194, NLR: 0.107)

8.2.3 Sleeping State

In the sleeping state, EAR was persistently low across all frames (mean 0.140), well below the 0.20 threshold, indicating sustained eye closure consistent with Stage 1 sleep onset. MOR was low (mean 0.016), suggesting the subject had progressed beyond the active yawning phase into early sleep. Stable NLR (0.101) reflects a stationary resting posture. These combined readings are characteristic of a driver who has entered light sleep in a real-time system, such readings would immediately trigger a sustained alert [Fig.9]

Fig.9. Facial metric graph — Sleeping state (EAR: 0.140, MOR: 0.016, NLR: 0.101)

8.2.4 Head Bending State

The head bending condition yielded a distinctive metric signature: EAR remained within the normal awake range (mean 0.321), indicating the eyes were still open, while NLR was significantly depressed (mean 0.073) well below the neutral 0.90–1.10 baseline. This reduction reflects a forward chin tilt reducing the perceived vertical nose length. MOR was slightly elevated at 0.033 relative to the sleeping state, attributable to light mouth movement during early fatigue. The combination of a normal EAR with a low NLR provides an early-fatigue indicator that precedes eye closure, enabling pre-emptive alerting before the driver enters a more advanced drowsiness stage [Fig. 10]

Fig.10. Facial metric graph — Head Bending state (EAR: 0.321, MOR: 0.033, NLR: 0.073)

9. Conclusions

This paper presented and experimentally validated an integrated ADAS framework comprising three complementary safety modules for electric vehicles. The Forward Collision Avoidance System reliably applied automatic braking whenever obstacles were detected within the 50 cm threshold, with no false triggers recorded. The Blind Spot Detection system accurately produced directional LED and audible alerts for all tested scenarios across left, right, and rear sensor channels. The Driver Drowsiness Detection system successfully classified four distinct driver states: Active, Drowsy, Sleeping, and Head Bending using a three-parameter facial metric model (EAR, MOR, NLR). Notably, the EAR+NLR combination provided a sensitive early-fatigue indicator that precedes full eye closure, enabling pre-emptive alerting at the head-bending stage before dangerous drowsiness sets in.

The system is constructable at approximately USD 25 for the sensor hardware modules, is fully modular and independently testable per subsystem, and offers a practical safety upgrade for commuter-segment vehicles currently underserved by commercial ADAS products. The proposed architecture can serve as a foundational platform for more sophisticated future implementations.
